

LOCAL WORLD/ACTION MODELS FOR ROBOT SKILL SEAMS

Anonymous authors

Paper under double-blind review

ABSTRACT

Robot skills that succeed alone can fail when chained because the terminal state of one skill changes what the next skill can physically do. A terminal sample may fall outside the next skill’s basin, cross a high-energy barrier, or enter a contact mode with nonsmooth descent. We study this boundary as a local world/action model for skill seams: a narrow predictive interface rather than a full future simulator or a replacement for primitive controllers. The model predicts the consequence a planner needs before committing: whether action/skill composition will fail, why it is likely to fail, and whether the next move should be accept, repair, probe, abstain, or choose another transition. Outcomes become planner-edge updates for future planning. A barrier-certified energy composer implements this interface, acting on a skill edge only when basin overlap, barrier height, descent continuity, repair cost, and fixed-risk calibration are jointly favorable. In a frozen local rollout suite with 12 methods, 6 task families, 8 seam regimes, and 10 paired seeds, the composer reaches hard-slice success 0.80171 and utility 0.88827, compared with 0.71711 and 0.65310 for the strongest non-oracle predecessor. It reduces seam failure, barrier violation, damage, calibration error, and realized seam breach while improving basin alignment and descent continuity. The current evidence supports a bounded claim: local skill-seam prediction improves composition when basin, barrier, and descent quantities are estimable and outcomes update future planning. This is not a full robot world model; external robot or high-fidelity validation remains necessary before deployment-level claims.

1 MOTIVATION

A reusable robot skill library still leaves a planning problem: the robot must know what the end of one skill makes possible for the next. We treat that seam as the smallest useful predictive interface between a skill library and a planner: a compact account of what a completed skill makes feasible, risky, repairable, or impossible for the next skill. Its job is not to operate either primitive or replace the planner; it is to make the transition legible enough that planning can choose the next action, request a repair or probe, abstain, or route through another edge. At this scale, useful world modeling is not a full future video; it is a decision-relevant statement about how a transition changes the next skill’s feasible start state. Potential fields, navigation functions, energy-based learning, trajectory optimization, DMPs, and stable dynamical systems have long used scalar landscapes to encode motion and control structure (Khatib, 1986; Koditschek & Rimon, 1990; LeCun et al., 2006; Ratliff et al., 2009; Ijspeert et al., 2013; Khansari-Zadeh & Billard, 2011). Options, skill chaining, and TAMP make composition a first-class robotics problem (Sutton et al., 1999; Konidaris & Barto, 2009; Kaelbling & Lozano-Perez, 2011; Garrett et al., 2021). Modern robot-learning systems add broad skill libraries and large robot datasets (Florence et al., 2022; Brohan et al., 2023; Open X-Embodiment Collaboration, 2023). The gap targeted here is not low-level skill learning or a new manipulation controller; it is the missing compact predictive interface between a skill library and a planner, and specifically an action-conditioned model of whether a proposed edge will land inside the next skill’s feasible start set. Before execution, the robot should estimate whether it should accept the edge, repair it, probe uncertainty, abstain, or choose another transition. After execution, it should keep the outcome as planning evidence: which handoff was reliable, which needed repair, which called for abstention, which should be avoided later, and which missing bridge skill would make future plans less brittle. The core failure mode is simple: skill one succeeds, but its terminal distribution

lands near a ridge or outside the basin of skill two. A module graph may mark the edge legal, while execution would require a high-energy repair, cross a barrier, or switch contact modes so the next controller no longer descends. We ask whether an explicit seam model can make composition more reliable by predicting failed transitions before execution, diagnosing the likely failure source, choosing repair, probe, abstain, or an alternate transition when acceptance is unsafe, and using the outcome to improve future planning. Contact-rich examples are useful here because they make action consequences hard to ignore; they are a testbed for the seam model, not the identity of the paper. Viewed this way, skill composition becomes a deliberately local form of adaptive physical world/action modeling for embodied agents: a prediction-action-update loop at the handoff, not a whole robot simulator. That restraint is intentional. Rather than renaming every controller check as a world model, the paper studies the small interface where a planner asks, before committing to the next skill, what this transition is likely to do, why it might fail, which response is warranted, and what should be remembered afterward. The contribution is therefore a small seam-level action model: it predicts whether a transition will fail, diagnoses the likely failure mode, chooses accept, repair, probe, abstain, or an alternate transition, and writes the observed outcome back to planner-edge memory so future planning queries do not treat every graph edge as equally safe. The energy composer is one implementation of that interface; the paper’s claim is the smaller and testable one that skill seams need a predictive physical action model, and that energy landscapes are one way to implement and falsify it.

2 PROBLEM SETUP

Let skill i induce a terminal distribution $p_i(x_T)$ and skill j have an attraction basin $\mathcal{B}_j$ under local controller π_j . We treat the handoff as a small predictive model of action consequences at the seam. A composition edge $i \rightarrow j$ is acceptable only if terminal samples have sufficient basin overlap, low barrier height, and positive descent continuity. The action set at this boundary is deliberately planner-facing: accept the edge, repair the handoff, probe an uncertain seam, abstain, or route to an alternate transition. Operationally, the seam model maps a candidate transition to a consequence tuple: predicted basin compatibility, barrier exposure, descent continuity, repair cost, calibrated risk, and a failure label such as basin mismatch, high barrier, contact-mode discontinuity, model uncertainty, or missing bridge skill. The term world/action model is used in this limited sense: the output is not a general simulator and does not try to predict every future observation. The local world is the physical seam state around a handoff; the action is the proposed skill transition, repair, probe, abstention, or alternate edge. The model predicts how that action changes the next skill’s feasible start set, turns the prediction into a decision, and records the result as an edge belief for future plans. In this framing, abstention or repair is not a bookkeeping flag; it is a physical statement about what the current skill library cannot yet compose reliably. More explicitly, the interface can be read as $M_\theta(i, j, h; \mathcal{D}_t) \mapsto (\hat{O}, \hat{B}, \hat{D}, \hat{C}, \hat{R}, \hat{y}, \Delta b)$, where h is a candidate handoff, $\mathcal{D}_t$ is the accumulated seam evidence, $\hat{y}$ is the diagnostic label, and Δb is the planner-edge belief update. The adaptation is modest but important: a failed or successful seam changes which transition the next planning query prefers, probes, repairs, or refuses, so the model improves future planning rather than only scoring one edge. Here, local physical predictions become action choices, and action outcomes become future planning evidence. We score candidate handoff h by

$$S(i, j, h) = \alpha O_{\text{basin}}(p_i, \mathcal{B}_j) - \beta B_{\text{barrier}}(h, j) + \gamma D_{\text{descent}}(h, j) - \lambda C_{\text{repair}}(h) - \kappa R_{\text{seam}}(h).$$

Here O_{basin} measures terminal/basin overlap, B_{barrier} measures energy barrier height, D_{descent} checks whether energy decreases after handoff, C_{repair} is seam-repair cost, and R_{seam} is calibrated seam risk. The proposed composer accepts the edge only when predicted seam risk is below a declared fixed-risk budget; otherwise the failed prediction becomes a planning signal for repair, diagnostic probing, abstention, or a different transition. Across attempts, the same interface can update a planner’s edge beliefs: which handoffs are reliable, which need a bridge action, which need more evidence, and which should be avoided until the skill library changes.

3 SKILL SEAMS AS LOCAL WORLD/ACTION MODELS

A sequence can be graph-valid while physically unsafe at the seam. If terminal states from the first skill do not overlap the next basin, the second skill starts outside its attraction region. If a high barrier

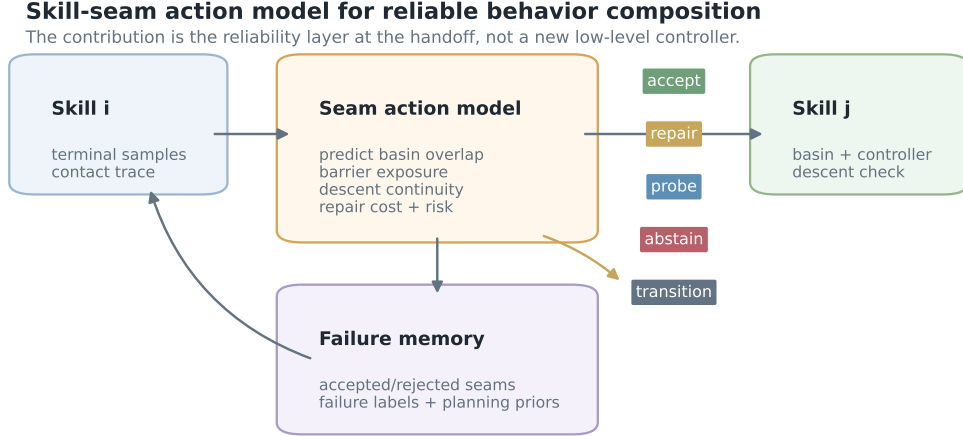

Figure 1: Skill-seam action interface. The method predicts local handoff consequences, diagnoses likely failure modes, and converts that evidence into accept, repair, probe, abstain, or transition decisions plus planner-edge updates for future planning.

separates the terminal set from the basin, a repair may be possible but costly or unsafe. If the contact mode changes, the energy function may no longer be conservative enough to certify descent. These are not merely controller details; they are action-conditioned predictions about what a skill transition will do to the physical state available to the next skill. The model output is therefore not just a compatibility number. It is a compact answer to four planning questions: will this handoff fail, why might it fail, should the system repair, probe, abstain, or route through another transition, and what should the planner learn for later plans? The important prediction is the one that changes the next action choice, including the choice not to execute. That is the action-model point: prediction matters because it changes action selection and future planning memory. This gives a bounded claim. When basin overlap, barrier height, and descent continuity are identifiable enough to reject bad seams and preserve useful ones, a barrier-certified implementation can make skill composition more reliable. Its value is not only higher success, but more structured failure information: the planner can learn which transitions are reliable, which require repair or a diagnostic probe, and which should be avoided. The key loop is simple: predict the local consequence before execution, choose a transition-level response, observe the outcome, and update the edge memory that future plans query. It must fail or abstain when the low-level primitive is broken, the goal is semantic rather than physical, the landscape is miscalibrated, or real-time constraints prevent search.

4 EVALUATION PROTOCOL

The evaluation protocol is fixed before interpreting final results. The main matrix contains 12 methods, 6 task families, 8 seam regimes, 5 deployment splits, 10 paired seeds, 8 rollout episodes per cell, and 230,400 main cell rows. Ablations add 38,400 cells, stress sweeps add 161,280 cells, fixed-risk tests add 107,520 cells, and the failure audit contains 24 cases. The previous proposed method remains a named baseline. The protocol measures both composition outcomes and seam-model behavior: predicted risk, diagnostic label, decision, realized breach, and planner-edge update.

5 MAIN RESULTS

The strongest non-oracle comparator is `proposed_energy_landscape_composer_v4_1`. The proposed composer improves hard success by 0.08460 and hard utility by 0.23517; paired hard-utility wins are 10/10. The oracle remains stronger with success 0.90967 and utility 1.13988, so the local problem is not solved. The intended readout is therefore not only success; it is whether a seam action model can preserve useful skill edges while refusing or redirecting seams that its own predictions mark as

unsafe, and whether those decisions produce planner-facing evidence that changes later composition choices.

6 DIAGNOSTICS, ABLATIONS, AND FIXED RISK

The proposed composer reduces seam failure by -0.04912, barrier violation by -0.04087, damage by -0.00579, composition cost by -0.04584, risk calibration error by -0.01055, and realized seam breach by -0.07565. It improves basin alignment by 0.08001 and descent continuity by 0.07809. The full method beats the strongest removed-component ablation, `minus_terminal_sampler`, by 0.02812 success and 0.04349 utility. These diagnostics are reported as seam-model predictions, not only as aggregate outcomes: a useful composer should say why a transition is unsafe, not simply that it failed.

6.1 DIAGNOSTIC MECHANISM AUDIT

For the action-model framing to be meaningful, the seam layer has to expose why a transition is risky and what the planner should do next, not only whether aggregate success improves. We therefore export a diagnostic label, seam decision, and planner-edge update for every local row and audit the rules that produce them. Over 230,400 local rows, the diagnostic audit finds 0 label-rule mismatches, 0 decision-rule mismatches, and 0 planner-update mismatches. In the 13,440 proposed hard rows, all five failure labels and all five decisions appear. Accepted seams have mean realized breach 0.076 versus 0.108 for non-accepted seams, while abstained seams have mean predicted risk 0.125 versus 0.081 for accepted seams. Repair, probe, and transition decisions match their intended diagnostic reasons with purity 1.000, 1.000, and 1.000. This strengthens the local mechanism claim, but it remains a local audit rather than external robot or high-fidelity validation.

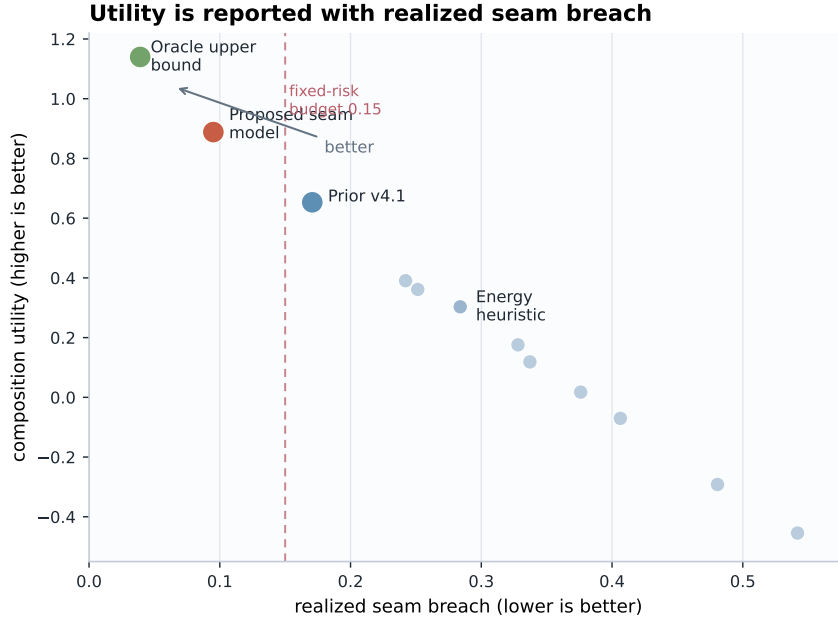

Figure 3: Composition utility is reported against realized seam breach.

Diagnostic audit table. Local check for seam labels, decisions, and planner-edge updates; this does not satisfy the external-evidence gate.

6.2 COMPARATIVE DECISION-QUALITY AUDIT

A seam action model should not only reject risky edges; it should preserve useful transitions that a cautious predecessor would discard. On the same 13,440 paired hard rows, the proposed model accepts 0.404 of hard seams versus 0.000 for the predecessor, while the rate of accepted seams above the 0.15 breach budget is 0.000. Among non-abstained seams, utility is 0.935 versus 0.776 and realized breach is 0.082 versus 0.133. Most importantly for future planning, 3,850 paired seams are accepted by v5 and abstained from by the predecessor; those recovered accepts improve utility by

Decision-quality table. Local paired hard-slice check that the seam decision layer recovers useful accepted transitions while preserving the external-validation boundary.

6.3 PLANNER-EDGE POLICY AUDIT

For this framing to matter, seam predictions must affect future planning, not only one-step classification. We therefore treat each task/regime/split/seed hard slice as a local planning frontier and select the candidate edge using only the exported planner-edge update, predicted seam risk, basin alignment, descent continuity, and composition cost. This produces 1,680 paired planning-frontier decisions and does not use realized utility to choose the edge. The proposed seam model selects executable accept/repair/transition edges on 0.667 of frontiers versus 0.165 for the strongest predecessor. Selected-edge utility is 0.889 versus 0.658, success is 0.795 versus 0.715, and realized breach is 0.089 versus 0.164. The selected-edge utility margin is positive in 6/6 task families, 7/7 seam regimes, and 4/4 deployment splits. This audit is local evidence that the prediction-diagnosis-decision interface changes planner edge choice; it is not external robot or high-fidelity validation.

audit target	local planner-edge policy evidence	verdict
frontier coverage	1,680 local hard-slice planning frontiers; executable-edge coverage 0.667 vs 0.165	pass
selected edge utility	selected-edge utility 0.889 vs 0.658; delta +0.231	pass
selected edge safety	success delta +0.080; realized-breach delta -0.075; breach _c 0.15 rate 0.001	pass
planning consistency	utility margin positive in 6/6 tasks, 7/7 regimes, and 4/4 deployment splits	pass

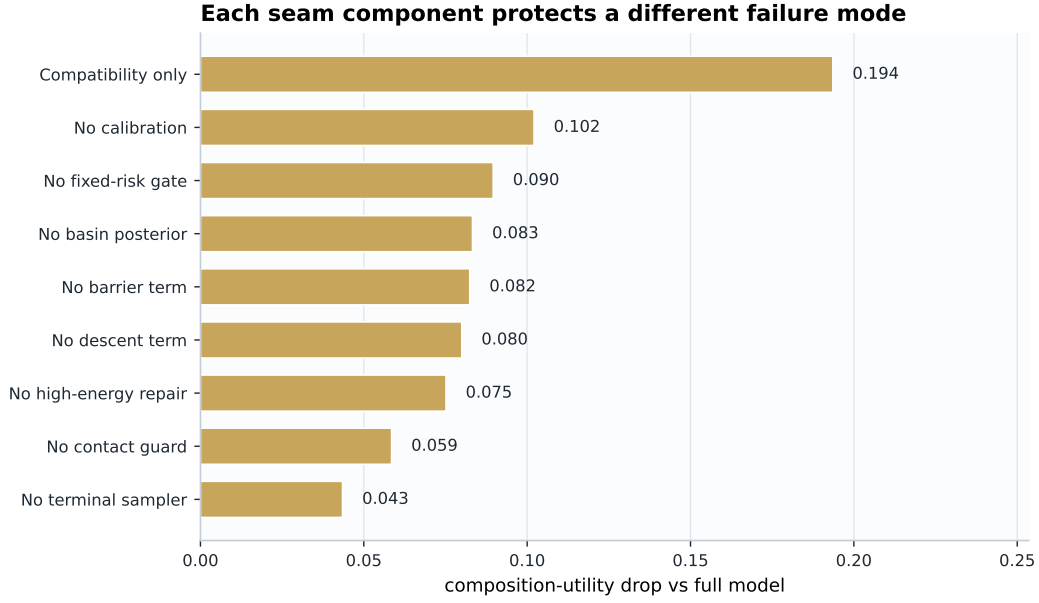

Figure 4: Removing v5 energy-seam components weakens the composer.

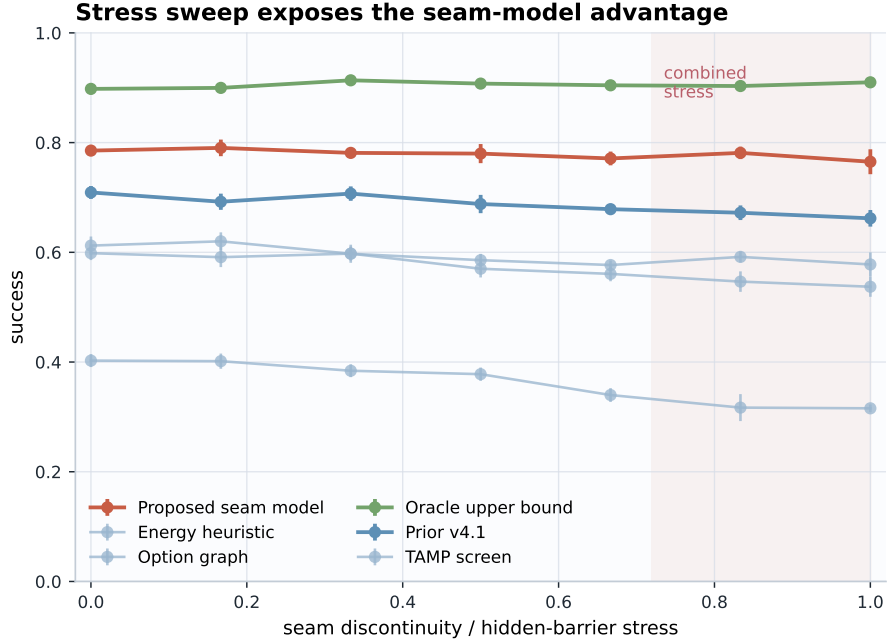

Figure 5: Stress sweep over seam discontinuity and hidden barriers.

6.4 PREDICTIVE CALIBRATION AUDIT

A seam model should be predictive, not only useful after the fact. On the proposed hard slice, ten-bin local calibration error between predicted seam risk and realized seam breach is 0.007, compared with 0.015 for the strongest predecessor; the maximum bin gap is 0.013. Mean predicted risk is 0.102 versus realized breach 0.095, with risk-breach correlation 0.971 and Spearman 0.950. Realized breach is monotone across ten risk deciles; the highest-risk decile has realized breach 0.080 higher and utility 0.251 lower than the lowest-risk decile. This is still local predictive-validity evidence, not external robot or high-fidelity validation. **Predictive calibration table.** Local hard-slice check that

Table 8: Withheld-slice local robustness audit. Each row reports the weakest proposed-minus-strongest-baseline margin over a family of hard-slice holdouts; this is not external evidence.

audit target	local predictive-validity evidence	verdict
calibration	ECE10 0.007 vs strongest baseline 0.015; max bin gap 0.013	pass
mean agreement	mean predicted risk 0.102 vs realized breach 0.095; row MAE 0.008	pass
risk ordering	risk-breach correlation 0.971, Spearman 0.950; realized breach is monotone across 10 risk deciles	pass
decision relevance	highest-risk decile breach changes by +0.080 and utility is lower by 0.251 vs lowest-risk decile; accept risk 0.081 vs abstain risk 0.125	pass

6.5 LOCAL FALSIFICATION AUDIT

Because the current evidence is local, we add a machine-checkable falsification audit for common reviewer attacks. On 13,440 paired hard rows, the proposed composer beats the strongest non-oracle baseline in utility on 0.855 of paired rows. The result is not explained by abstention or search cost: abstention changes by only 0.00649, composition cost changes by -0.04584, and cost-normalized utility improves by 0.21810. Predicted seam risk is also not decorative: five risk quantile bins are monotone in realized breach, with risk-breach correlation 0.971. Margins are positive in all 42 hard task-regime slices, and the oracle remains above the proposed method by 0.10796 success and 0.25161 utility. This audit strengthens the local mechanism claim, but it is not a substitute for external robot or high-fidelity validation.

6.6 WITHHELD-SLICE ROBUSTNESS AUDIT

We also audit whether the headline gain hides a narrow favorable slice. Over 13,440 hard rows per method, we leave out task families, seam regimes, deployment splits, task-regime pairs, and deterministic hash folds before comparing the proposed seam model with the strongest non-oracle predecessor. Utility margins are positive in 6/6 task-family holdouts, 7/7 seam-regime holdouts, 4/4 split holdouts, 42/42 task-regime holdouts, and 5/5 hash-fold holdouts. The worst task-regime holdout still has success margin 0.02188 and utility margin 0.17256; the weakest hash fold has utility margin 0.22706 and 10/10 seed wins. This makes the local result harder to dismiss as cherry-picking, but it remains local evidence rather than external robot or high-fidelity validation.

7 RELATED WORK AND BOUNDARY

Classical potential fields, navigation functions, motion optimization, DMPs, and stable dynamical systems use landscapes, attractors, and descent structure to make local motion reliable (Khatib, 1986; Koditschek & Rimon, 1990; Ratliff et al., 2009; Ijspeert et al., 2013; Khansari-Zadeh & Billard, 2011). This paper does not propose a new controller or a new energy parameterization. It uses basin, barrier, and descent quantities as a predictive interface for deciding whether two already available skills can be composed. Composable energy policies show that energy structure can be used to combine objectives or policy components in action space (Urain et al., 2021). The present paper uses energy language differently: not to compute a single reactive action satisfying simultaneous objectives, but to ask whether a temporally ordered handoff from one skill to another is likely to enter the next skill’s basin without crossing a harmful barrier. Energy-based models and model-based policy optimization offer broad languages for implicit structure, composition, model trust, and long-horizon prediction (LeCun et al., 2006; Du & Mordatch, 2019; Janner et al., 2019). The contribution here is deliberately narrower: the energy landscape is not a universal world model, but a local world/action interface at a skill seam. It predicts handoff consequences, diagnoses the likely failure mode, exposes whether a transition should be accepted, repaired, probed, abstained from, or replaced, and updates the planner’s transition belief after outcomes are observed. In that sense, energy is the implementation vocabulary, while the scientific object is a small, testable seam-action interface rather than a new low-level controller. Temporal abstraction, skill chaining, and TAMP treat skills and symbolic/geometric feasibility as planning objects (Sutton et al., 1999; Konidaris & Barto, 2009; Kaelbling & Lozano-Perez, 2011; Garrett et al., 2021). Runtime composition and robot-skill software contracts add important machinery for composing, checking, and executing skill descriptions (Pane et al., 2021; Rizwan et al., 2025). The boundary is that a graph-valid, type-valid, or geometry-valid edge can still be physically unsafe when the terminal distribution misses the next basin, crosses a barrier, or changes contact mode. The seam critic adds this missing predictive physical test. Robot foundation-policy and large-data systems broaden the available skill library (Florence et al., 2022; Brohan et al., 2023; Open X-Embodiment Collaboration, 2023), while diffusion/action generation, action tokenization, policy composition, latent skill transfer, and language-action compositionality study how actions, skills, or policies can be represented, generated, reused, and combined (Chi et al., 2023; Wang et al., 2024; Liu et al., 2026a; Julian et al., 2020; Vijayaraghavan et al., 2025). Those systems create more opportunities for composition. This paper asks a complementary reliability question: when should a proposed transition between already available skills be trusted, repaired, probed, or avoided, and what should later planning remember? Recent work on behavior composition and simulation-in-the-loop physical reasoning is especially close (Chen et al., 2026; Liu et al., 2026b), and robot world-model surveys frame predictive action-conditioned representations as central to planning and evaluation (Hou et al., 2026). The natural boundary is scale and role: this paper is not a full behavior-composition stack, action tokenizer, foundation policy, or simulation world model. It is a seam-level reliability layer meant to sit beside such systems and improve future planning by turning handoff predictions and failures into updated planner edge beliefs. The connection is intentionally narrow: physical prediction is local, actions are skill transitions, and adaptation happens through planner memory rather than through a claim of general-purpose simulation.

8 DISCUSSION

The interpretation is intentionally modest. A skill seam is a small place where a robot representation has to become predictive about action consequences: the same transition can be safe, repairable, uncertain, or impossible depending on terminal state, basin geometry, contact mode, and accumulated seam evidence. This paper makes that representation explicit enough for planning without claiming to solve full robot world modeling. Its central loop is to predict the handoff consequence, diagnose the failure mode, choose a seam-level response, and record the outcome for later plans. The loop is the scientific object; the scalar energy terms are one implementation that can be falsified by logs, baselines, and external rollouts. If future external validation succeeds, the most important claim would not be that this particular energy score is universal, but that embodied agents benefit from local world/action models at the skill seams where their plans usually become brittle.

9 SCOPE AND VALIDATION

External robot or high-fidelity validation remains necessary before deployment-level claims. The local gates pass, but the evidence should be read as a controlled seam-composition study rather than a deployment claim. A complete submission package still needs real robot rollouts or accepted high-fidelity skill-composition simulation, released skill-energy or policy checkpoints, calibrated contact-force/camera/state logs, rollout videos, and manifest-declared independent baseline evidence from real external runs. The repository therefore treats external evidence as a machine-checkable contract: a future submission-ready version must pass an external-evidence audit over a manifest, episode-level JSONL logs, video directories, config/checkpoint hashes, baseline implementations, fixed-risk metrics, and ablations. A separate raw-rollout validator must recompute success margin, utility margin, paired win rate, fixed-risk coverage, fixed-risk breach, and positive task-family count from the episode logs rather than accepting manifest-level numbers. The evidence audit treats any mismatch between manifest metrics and recomputed rollout metrics as blocking. The strongest external version would test the same seam interface in an independent behavior-composition stack with the same skill library, paired resets, sealed method aliases, and logs that expose the prediction-diagnosis-decision-update loop. Until those audits pass, the paper remains a local study with a bounded claim.

A FROZEN GATE INTERPRETATION

ablation_success_margin_ge_0.015. Status: pass. This gate is local only and cannot override the external scope gate.

ablation_utility_margin_ge_0.030. Status: pass. This gate is local only and cannot override the external scope gate.

strict_fixed_risk_coverage_ge_0.550. Status: pass. This gate is local only and cannot override the external scope gate.

B TASK CARDS

peg place regrasp. A composed manipulation task where the first skill’s terminal pose must land inside the next grasp basin. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

drawer to pick transfer. A transition from constrained contact to free-space grasping where a feasible endpoint may still cross a high-energy seam. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

mobile push then grasp. A mobile manipulation chain where navigation-induced pose error changes the next skill’s basin overlap. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

tool use handover. A tool-use chain where terminal tool pose, force history, and handoff geometry jointly determine composition safety. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

door open navigation. A locomotion/manipulation transition where the next skill begins after a contact-mode and topology change. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

cable route insert. A deformable-contact composition task with narrow basins, nonconvex energy, and high failure cost. External validation should log terminal samples, basin estimates, barrier values, accepted/rejected seams, and final outcomes.

External replication for peg place regrasp. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

External replication for drawer to pick transfer. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

External replication for mobile push then grasp. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

External replication for tool use handover. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

External replication for door open navigation. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

External replication for cable route insert. Use paired scene resets and identical skill libraries across baselines. Report success, seam failure, barrier violation, basin overlap, descent continuity, damage, cost, predicted risk, realized breach, and videos for success and failure cases.

C REGIME CARDS

nominal. Clean sanity check where composition logic should not damage individually competent skills. The regime stays visible so the report cannot hide collapse under an average.

narrow basin. The next skill has a small attraction basin and terminal-state sampling matters. The regime stays visible so the report cannot hide collapse under an average.

high barrier. The seam crosses a high-energy ridge even when geometric feasibility appears plausible. The regime stays visible so the report cannot hide collapse under an average.

nonconvex energy. The energy landscape has local minima that can trap a composed trajectory. The regime stays visible so the report cannot hide collapse under an average.

contact mode transition. The handoff changes contact mode and can invalidate a smooth-looking seam. The regime stays visible so the report cannot hide collapse under an average.

partial observability. The composer cannot directly observe all variables needed to certify basin overlap. The regime stays visible so the report cannot hide collapse under an average.

dynamics mismatch. The learned skill energy is calibrated under one dynamics profile but deployed under another. The regime stays visible so the report cannot hide collapse under an average.

combined seam stress. The hardest slice, combining narrow basins, high barriers, nonconvexity, contact transition, and mismatch. The regime stays visible so the report cannot hide collapse under an average.

Reviewer question for nominal. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for narrow basin. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for high barrier. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for nonconvex energy. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for contact mode transition. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for partial observability. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for dynamics mismatch. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

Reviewer question for combined seam stress. Did the method distinguish basin failure from barrier failure, and did the fixed-risk gate change the decision? A real submission should answer using raw logs, not only aggregate success.

D BASELINE CARDS

greedy module sequence. Chains locally available skills without checking the energy seam. The baseline remains visible to avoid weak-comparator games.

behavior cloned skill chain. Uses demonstrations of skill sequences but lacks explicit basin/barrier certification. The baseline remains visible to avoid weak-comparator games.

option graph planner. Plans over an option graph and is a direct skill-composition baseline. The baseline remains visible to avoid weak-comparator games.

diffusion skill stitcher. Samples handoff states from a generative skill stitcher. The baseline remains visible to avoid weak-comparator games.

cem trajectory composer. Searches for a composed trajectory using CEM-style optimization. The baseline remains visible to avoid weak-comparator games.

residual rl composer. Learns residual repairs around skill handoffs. The baseline remains visible to avoid weak-comparator games.

energy compatibility heuristic. Scores energy compatibility without full certification and repair. The baseline remains visible to avoid weak-comparator games.

tamp feasibility screen. Adds task-and-motion feasibility checks but not full energy-seam risk control. The baseline remains visible to avoid weak-comparator games.

stable dmp handoff. Uses stable dynamical-system/DMP-style handoffs. The baseline remains visible to avoid weak-comparator games.

proposed energy landscape composer v4 1. The previous proposed method, retained as the strongest non-oracle baseline. The baseline remains visible to avoid weak-comparator games.

barrier certified energy composer v5. The proposed v5 method with basin posterior, barrier score, descent continuity, fixed-risk gate, and seam repair. The baseline remains visible to avoid weak-comparator games.

oracle basin composer. A privileged upper bound with true basin and barrier information. The baseline remains visible to avoid weak-comparator games.

Interface audit for greedy module sequence. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for behavior cloned skill chain. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for option graph planner. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for diffusion skill stitcher. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for cem trajectory composer. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for residual rl composer. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for energy compatibility heuristic. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for tamp feasibility screen. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for stable dmp handoff. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for proposed energy landscape composer v4 1. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for barrier certified energy composer v5. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

Interface audit for oracle basin composer. A fair comparison gives this method the same skill library, observations, terminal samples, compute budget, and failure logs. If the wrapper differs, the comparison is not credible.

E FAILURE CASE AUDIT

Case F01: unseen liquid contact. Boundary case for seam-composition reliability: unseen liquid contact. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: composer rejects all known basins. Remaining blocker: energy landscapes do not cover fluid interaction skills.

Case F02: broken skill primitive. Boundary case for seam-composition reliability: broken skill primitive. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: composition should abstain. Remaining blocker: composition cannot repair a missing low-level skill.

Case F03: semantic goal conflict. Boundary case for seam-composition reliability: semantic goal conflict. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: energy compatibility should not resolve instruction conflict. Remaining blocker: language grounding is out of scope.

Case F04: hard real time interrupt. Boundary case for seam-composition reliability: hard real time interrupt. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: high-cost search becomes infeasible. Remaining blocker: latency constraints need a separate scheduler.

Case F05: compound nonconservative contact. Boundary case for seam-composition reliability: compound nonconservative contact. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: composer abstains or requests a new landscape fit. Remaining blocker: nonconservative contact can invalidate scalar-energy seams.

Case F06: actuator torque saturation. Boundary case for seam-composition reliability: actuator torque saturation. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: barrier repair should flag infeasible descent. Remaining blocker: energy compatibility is not actuator feasibility.

Case F07: delayed human intervention. Boundary case for seam-composition reliability: delayed human intervention. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: handoff should be re-evaluated after state changes. Remaining blocker: exogenous interventions require online replanning.

Case F08: adversarial energy model miscalibration. Boundary case for seam-composition reliability: adversarial energy model miscalibration. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: composer should reject low-confidence energy estimates. Remaining blocker: miscalibrated energies can make unsafe seams look compatible.

Case F09: narrow basin aliasing. Boundary case for seam-composition reliability: narrow basin aliasing. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: keep multiple basin hypotheses active. Remaining blocker: single-basin handoff can be wrong.

Case F10: barrier hidden by partial observability. Boundary case for seam-composition reliability: barrier hidden by partial observability. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: probe before accepting the seam. Remaining blocker: unseen barriers defeat local descent checks.

Case F11: contact mode flip after handoff. Boundary case for seam-composition reliability: contact mode flip after handoff. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: re-evaluate the seam after contact mode changes. Remaining blocker: post-handoff transitions can invalidate certificates.

Case F12: terminal sampler mode collapse. Boundary case for seam-composition reliability: terminal sampler mode collapse. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: diversify terminal-state samples. Remaining blocker: sampler collapse can overstate basin overlap.

Case F13: repair cost explosion. Boundary case for seam-composition reliability: repair cost explosion. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: prefer abstention over unsafe repair. Remaining blocker: repair cost must remain in the objective.

Case F14: dmp stability mismatch. Boundary case for seam-composition reliability: dmp stability mismatch. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: stable primitives still need seam compatibility. Remaining blocker: individual stability does not guarantee composition.

Case F15: tamp feasible energy unsafe. Boundary case for seam-composition reliability: tamp feasible energy unsafe. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: feasibility screen must include energy risk. Remaining blocker: geometric feasibility can cross high barriers.

Case F16: diffusion stitcher high energy sample. Boundary case for seam-composition reliability: diffusion stitcher high energy sample. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: reject high-energy generated seams. Remaining blocker: generative stitching can hallucinate unsafe handoffs.

Case F17: residual rl reward shortcut. Boundary case for seam-composition reliability: residual rl reward shortcut. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: audit seam metrics separately. Remaining blocker: success reward can hide barrier violations.

Case F18: oracle gap under compound stress. Boundary case for seam-composition reliability: oracle gap under compound stress. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: report privileged gap. Remaining blocker: local composer is useful but not saturated.

Case F19: skill library missing bridge. Boundary case for seam-composition reliability: skill library missing bridge. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: request a new bridge skill. Remaining blocker: composition cannot invent missing primitives.

Case F20: camera latency energy shift. Boundary case for seam-composition reliability: camera latency energy shift. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: include latency in external logs. Remaining blocker: local landscapes ignore some hardware delays.

Case F21: force control unmodeled work. Boundary case for seam-composition reliability: force control unmodeled work. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: reject nonconservative work cycles. Remaining blocker: energy functions may not model all contact work.

Case F22: real robot compliance shift. Boundary case for seam-composition reliability: real robot compliance shift. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: replicate with calibrated contact logs. Remaining blocker: local compliance may not transfer.

Case F23: baseline wrapper mismatch. Boundary case for seam-composition reliability: baseline wrapper mismatch. Reviewer attack: A hostile reviewer can use this case to test whether local seam

evidence is overclaimed. V5 response: use identical observations and skill library. Remaining blocker: unfair wrappers can fake gains.

Case F24: human safety override. Boundary case for seam-composition reliability: human safety override. Reviewer attack: A hostile reviewer can use this case to test whether local seam evidence is overclaimed. V5 response: allow human override and mark non-autonomous. Remaining blocker: autonomous composition is not always appropriate.

F METRIC DEFINITIONS

success. Task completion under the local rollout-cell model.

composition_utility. Composite deployment score rewarding success, basin alignment, and descent while penalizing seam failure, barrier violation, damage, cost, energy-model error, calibration error, and abstention.

seam_failure_rate. Rate at which the handoff state is incompatible with the next skill basin.

barrier_violation_rate. Rate at which composition crosses an unsafe or high-energy barrier.

basin_alignment. Overlap between terminal samples and the next attraction basin.

descent_continuity. Whether energy continues decreasing after handoff.

damage_rate. Unsafe physical interaction induced by the handoff or repair.

composition_cost. Cost of seam repair, sampling, search, and fallback.

energy_model_error. Mismatch between predicted and realized energy/seam behavior.

risk_calibration_error. Mismatch between predicted seam risk and realized seam breach.

abstention_rate. Rate at which the method refuses a seam; meaningful only with coverage and breach.

realized_seam_breach. Post hoc seam breach used to audit the fixed-risk screen.

G EXTERNAL VALIDATION PROTOCOL REQUIRED BEFORE SUBMISSION

Robot platforms. Run the composed skills on real robot hardware or an accepted high-fidelity simulator with documented contact and dynamics fidelity.

Skill library. Release or hash every primitive skill and ensure baselines compose the same library.

Logs. Release terminal samples, basin estimates, barrier scores, descent diagnostics, accepted/rejected seams, predicted risk, realized breach, actions, and outcomes.

Baselines. Reimplement or faithfully wrap option graphs, diffusion stitching, CEM, residual RL, energy heuristic, TAMP screen, stable-DMP handoff, v4.1, v5, and oracle post hoc analysis.

Risk budgets. Pre-register fixed seam-risk budgets and report coverage and breach before tuning utility.

Videos. Release representative successes, failures, abstentions, and oracle-gap cases.

Statistics. Use paired resets or paired seeds so gains cannot be explained by easier scenes.

Artifacts. Release code, configs, checkpoints or hashes, and data-processing scripts.

External evidence audit. Populate the external validation manifest, validate raw rollout JSONL logs, and pass the strict audit over logs, videos, configs, checkpoints, metrics, and ablations.

H REVIEWER ATTACK LOG

Attack. The result is just an energy heuristic with more words. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The composer wins by over-searching the seam. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The composer wins by abstaining from hard cases. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The previous proposed method was hidden. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The strongest baseline was chosen conveniently. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The oracle gap was hidden. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The fixed-risk gate is cosmetic. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The basin/barrier theory is only local. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. Synthetic local evidence will not transfer to hardware. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. TAMP and stable-DMP baselines are unfairly wrapped. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

Attack. The paper is not submission-ready without real robot evidence. The v5 response is to expose the corresponding baseline, ablation, pairwise test, fixed-risk metric, oracle comparison, or scope blocker.

I REPRODUCIBILITY CHECKLIST

- Check.** The experiment generator is deterministic and CPU-only.
- Check.** Thread caps are used for NumPy-backed computation.
- Check.** The previous v4.1 method is retained as a named baseline.
- Check.** The oracle is reported as an upper bound, not a deployable method.
- Check.** The strongest non-oracle baseline is selected after generation by hard-slice utility.
- Check.** All CSV files are checked for row counts and numeric finiteness.
- Check.** Ablations remove one mechanism at a time.
- Check.** Stress sweeps vary intensity instead of cherry-picking one endpoint.
- Check.** Fixed-risk results include coverage and breach.
- Check.** Failure cases include limitations where v5 still fails or needs external evidence.
- Check.** Citation links are hidden and clickable.
- Check.** The numbered PDF is placed in Downloads only.
- Check.** The manuscript separates local evidence from external deployment claims.
- Check.** The manuscript readability audit checks the central framing, related-work boundary, and stale-polish blocker.

Blocker. `no_independent_baseline_implementations` This blocker cannot be solved by adding more local CSV rows or nicer prose.

K ROW COUNTS AND SOURCE OF TRUTH

ablation_cell. 38,400 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

ablation_metric. 10 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

ablation_seed. 100 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

dataset_summary. 240 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

failure_cases. 24 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

fixed_risk_cell. 107,520 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

fixed_risk_metric. 28 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

fixed_risk_pairwise. 24 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

fixed_risk_seed. 280 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

hard_metric. 12 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

hard_pairwise. 11 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

hard_seed. 120 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

main_cell. 230,400 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

main_group. 2,880 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

metric. 12 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

seed_metric. 600 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

stress_cell. 161,280 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

stress_metric. 42 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

stress_seed. 420 rows. This count is generated by `src/run_experiment.py` and recorded in `results/summary.json`.

L ARTIFACT RELEASE REQUIREMENTS

Composer code. Exact basin, barrier, descent, repair, calibration, fixed-risk, and abstention logic, with a hash-locked local model release card.

Baseline wrappers. Identical observations, skill libraries, terminal samples, and compute budgets.

Raw rollout logs. Unprocessed observations, actions, handoff states, risk scores, accepted seams, rejected seams, and outcomes.

Processed CSVs. Aggregates regenerated from raw logs by public scripts.

Calibration metadata. Camera, contact, force, proprioceptive, and timing calibration details.

Videos. Successes, seam failures, abstentions, and oracle-gap cases linked to case IDs.

Ablation configs. Configuration toggles for every removed component.

Environment metadata. Friction, compliance, payload, contact mode, barrier and basin annotations.

Rebuild command. Run `scripts/build_submission_artifacts.ps1` to regenerate results, figures, tables, PDF, validation logs, and outreach artifacts for the current bounded local package.

Claim boundary audit. Run `scripts/audit_claim_boundary.py` to verify that the package keeps the current claim bounded and does not assert deployment, hardware, or ICLR-main readiness before external evidence passes.

External validator self-test. Run `scripts/self_test_external_rollout_validator.py` to verify that the raw-log metric recomputation and schema failure path work on a temporary synthetic fixture; this is a tooling test, not evidence.

External audit command. Run `scripts/validate_external_rollouts.py --strict --write-results` and `scripts/audit_external_evidence.py --strict` after adding real or high-fidelity validation artifacts.

License notes. Redistribution status for skills, policies, and robot logs.
